- 21 Running Title: Evaluation of a *Glaesserella parasuis* capsule mutant
- 22
- 23 #Address correspondence to Susan L. Brockmeier, susan.brockmeier@ars.usda.gov

25 *Glaesserella (Haemophilus) parasuis* is a commensal of the upper respiratory tract in pigs and 26 also the causative agent of Glässer's disease, which causes significant morbidity and mortality in 27 pigs worldwide. Isolates are characterized into 15 serovars by their capsular polysaccharide, 28 which has shown a correlation to isolate pathogenicity. To investigate the role capsule plays in 29 G. parasuis virulence and host interaction, a capsule mutant of the serovar 5 strain HS069 was 30 generated (HS069 $\Delta$ cap) through allelic exchange following natural transformation. HS069 $\Delta$ cap 31 was unable to cause signs of systemic disease during a pig challenge study and had increased 32 sensitivity to complement killing and phagocytosis by alveolar macrophages. When compared to 33 the parent strain, HS069 $\Delta$ cap produced more robust biofilm and adhered equivalently to 3D4/31 34 cells; however, it was unable to persistently colonize the nasal cavity of inoculated pigs, with all 35 pigs clearing HS069∆cap by 5 days post-challenge. Our results indicate the importance of 36 capsular polysaccharide to G. parasuis virulence as well as nasal colonization in pigs.

37

39 *Glaesserella (Haemophilus) parasuis* is the etiologic agent of Glässer's disease in pigs, 40 which presents as a fibrinous polyserositis, arthritis and meningitis (1, 2). In addition, it can be a 41 bacterial contributor to swine respiratory disease and is found as a commensal in the nasal cavity 42 of healthy swine (1). *G. parasuis* isolates are classified into 15 serovars, based on gene content 43 and diversity at their capsular polysaccharide loci and via the Kielstein-Rapp-Gabrielson typing 44 scheme (3, 4). While it appears some serovars are more pathogenic and widespread, serotyping 45 has shown an incomplete correlation with isolate virulence (3, 5, 6).

46 The importance of capsular polysaccharide as a virulence factor for encapsulated bacteria 47 has been investigated (7-10), which indicates the capsule-deficient counterparts to encapsulated 48 bacteria are much less likely to cause invasive disease and are often reduced to avirulence. The 49 reduction in virulence seen in capsular mutants has been attributed to the role that capsule plays 50 in adherence to host tissues and evasion of the host immune response, specifically inhibition of 51 complement mediated killing and phagocytosis (11). Additionally, there is evidence indicating 52 capsular polysaccharide is essential for some encapsulated bacteria to colonize the mucous 53 membranes of hosts (12).

54 The functions of capsule have been partially evaluated in *G. parasuis* SH0165, a virulent 55 serovar 5 strain (10). The capsular mutant (SH0165∆capD) was significantly less virulent than 56 the wild type bacteria and unable to cause invasive disease in challenged pigs (10). SH0165∆cap 57 was also highly susceptible to complement mediated killing as compared to the wild type 58 bacteria (10). This presented evidence for the importance of capsule in causing invasive disease; 59 however, the characteristics of the capsular mutant were not fully elucidated and the capacity of 58 SH0165∆cap to colonize the swine nasal cavity was not evaluated. In this study, a capsule

61	mutant of G. parasuis HS069 (HS069∆cap), a virulent serovar 5 strain, was used to examine the
62	in vitro and in vivo characteristics of capsule. We evaluated HS069∆cap for susceptibility to
63	complement killing, biofilm formation, attachment to porcine macrophage 3D4/31 cells, and
64	phagocytosis by porcine alveolar macrophages. In addition, swine were challenged with HS069
65	and HS069∆cap to evaluate virulence, capacity for nasal colonization, and stimulation of host
66	immunity.

Accepted Manuscript Posted Online

### 68 Materials and Methods

#### 69 Bacterial isolates

70 The virulent serovar 5 G. parasuis strain HS069 was isolated from the lung of a pig with clinical

71 signs of respiratory disease (13). Production and verification of HS069∆cap is described within

the following mutant generation and results sections. G. parasuis strains were grown on brain

73 heart infusion (BHI) plates or BHI broth (Becton, Dickinson and Company, Franklin Lakes, NJ)

- supplemented with 0.1 mg/mL nicotinamide adenine dinucleotide (NAD+) and 10% horse serum
- 75 (referred to as BHI+). G. parasuis strains were also grown on chocolate agar, made with
- 76 Columbia Blood Agar Base (Thermo Fisher Scientific Inc., Waltham, MA) supplemented 7%
- defibrinated horse blood (TCS Bioscience Ltd., Botolph Claydon, England) lysed at 80°C for 10
- 78 minutes and 25 µg/mL NAD+. Media were supplemented with chloramphenicol (1 µg/mL) for
- relation purposes. All strains were grown at 37°C with 5% CO<sub>2</sub>.
- 80 Escherichia coli strain TOP10 (Invitrogen, Carlsbad, CA) was used as the cloning host. E. coli

81 was grown in Luria Bertani (LB) broth or agar (Oxoid). Media were supplemented with

82 ampicillin (100  $\mu$ g/mL) or chloramphenicol (50  $\mu$ g/mL) where required for selection.

### 83 Mutant construction

84 DNA manipulation: Genomic DNA extractions were performed using the DNeasy Kit (Qiagen,

- 85 Hilden, Germany), plasmid DNA extractions were performed using a plasmid miniprep kit
- 86 (Qiagen), and PCRs were performed according to the manufacturers' protocols with Phusion
- 87 High-Fidelity DNA Polymerase mix (New England Biolabs, Ipswich, MA) for cloning and
- 88 GoTaq green PCR mix (Promega, Madison, WI) for verification. PCR fragments purified by
- 89 QIAquick PCR Purification Kit (Qiagen). Restriction enzymes were obtained from New England

 $\triangleleft$ 

90

91	DNA concentrations were measured using a NanoDrop (Bio-Rad Laboratories, Hercules, CA).
92	Construction of plasmid pGEMT-neuAup-Cm-wzsdn: Plasmid pGEMT-neuAup-cat-wzsdn was
93	constructed for deletion of the whole capsule gene cluster using a three-step cloning strategy.
94	First, genomic DNA of G. parasuis isolate HS069 was used as a template to amplify the
95	upstream and downstream regions flanking the 14-kb capsule locus (14, 15). The 647-bp
96	upstream region of the neuA gene (neuAup) was amplified using primers P1 and P2 and the 731-
97	bp downstream region of the wzs gene (wzsdn) using primers P3 and P4 (Table 1). In parallel,
98	the chloramphenicol resistance cassette (Cm), containing the 9-bp DNA uptake signal sequence
99	(USS) of 5'-ACCGCTTGT (16) was amplified from 50 ng linearized plasmid pUSScat (17) as
100	the template with primers P5 and P6 (Table 1). Second, PCR products were digested and ligated
101	into the pGEM-T vector. The PCR product of the upstream region of the neuA gene was digested
102	with SacI /BamHI and the downstream region of the wzs gene was digested with SalI/ BamHI.
103	The pGEM-T vector was digested with SacI /SalI. Restricted products were gel purified and
104	ligated. The constructed plasmid was transformed into E. coli TOP10 and transformants were
105	confirmed using PCR. After purification, the plasmid pGEMT-neuAup-wzsdn was verified by
106	Sanger sequencing. Finally, the purified plasmid pGEMT-neuAup-wzsdn and PCR product of
107	the Cm cassette were subject to BamHI restriction. The gel purified fragments were mixed,
108	ligated and transformed into E. coli TOP10. The resulting plasmid pGEMT-neuAup-cat-wzsdn
109	was extracted and confirmed by Sanger sequencing.
110	Construction of the whole capsule locus deletion mutant $\Delta cap$ :: Cm mutant of G. parasuis
111	HS069: The plasmid pGEMT-neuAup-cat-wzsdn was linearized with SacI and used to transform
112	G. parasuis HS069 using natural transformation method as described previously with some

Biolabs. Plasmid DNA was extracted from the agarose gel using Gel Extraction Kit (Qiagen).

113

114	BHI broth to achieve an $OD_{660} = 2$ . Then, a 20 µl aliquot of a 1/10 dilution of the suspension was
115	spread in a 10 mm area on prewarmed chocolate agar and 20 $\mu l$ of 8 mM cAMP and 10 $\mu l$ of
116	donor DNA in TE buffer were added and mixed with the bacterial cells. The mixture was
117	incubated at 37°C overnight. Bacterial cells were scraped up, suspended in 300 µl BHI broth, and
118	plated onto chocolate agar with 1 ug/mL chloramphenicol. After incubation at 37°C for 2 days,
119	suspected transformants were verified using PCR. For negative control, 10 $\mu$ l of TE buffer
120	without donor DNA was added to a bacterial spot. The deletion was also confirmed by whole
121	genome sequencing using the Illumina HiSeq 250 platform and PacBio RS II Resequencing
122	protocol of the SMRT Analysis software v.2.3.0. Assembly of the PacBio generated HS069 wild
123	type was done using HGAP (19), circularized using Circlator v.1.1.3 (20), and polished using
124	Quiver v.1. The Illumina reads were subsequently mapped onto the PacBio assembly to correct
125	small indels. Comparison of HS069 $\Delta$ cap against the wild type was made by mapping the
126	Illumina and PacBio reads of HS069∆cap against the finished HS069 wild type assembly.
127	Transmission electron microscopy (TEM) for capsule visualization
128	Capsule was visualized via transmission electron microscopy (TEM) using previously described
129	methods (21-23). Briefly, G. parasuis grown on BHI+ plates overnight were suspended in 0.1 M
130	cacodylate buffer with 2.5% glutaraldehyde and 0.1% ruthenium red and incubated for 2 hours at
131	room temperature. Bacteria were pelleted and resuspended in 0.1 M cacodylate buffer with 2.5%
132	glutaraldehyde and 1.0 mg/mL of polycationic ferritin and incubated for 30 minutes at room
133	temperature. Bacteria were washed three times in 0.1 M cacodylate buffer. After staining with
134	ruthenium red and ferritin, samples were post-fixed with 2% osmium tetroxide and rinsed three
135	times in 0.1 M cacodylate buffer. The samples were processed through graded ethanols,

modifications (18). Briefly, HS069 was grown on chocolate agar overnight and suspended in

 $\overline{\mathbb{A}}$ 

136 propylene oxide, and embedded in Eponate 12 (Ted Pella Inc., Redding, CA). Following a 48 137 hour polymerization, thin sections were taken and stained with 4% uranyl acetate and Reynolds' lead stain. Sections were examined with a FEI Tecnai G<sup>2</sup> BioTWIN electron microscope (FEI 138 139 Co., Hillsboro, OR). 140 **Growth kinetics** 141 Growth kinetics of G. parasuis HS069 and HS069∆cap were evaluated using a GeneQuant Pro 142 spectrophotometer (Amersham PLC, Little Chalfont, United Kingdom). G. parasuis isolates 143 were inoculated from a liquid overnight culture into BHI+ broth at an  $OD_{600}$  of 0.05. The

144 cultures were incubated at 37°C with 5% CO2 and shaking at 200 RPM. OD600 readings were 145 taken hourly for 8 hours.

#### 146 Biofilm assay using microtiter plate

147 The microtiter plate assay for biofilm formation was adapted from a protocol described by Cassat 148 et al. (24). Overnight cultures of G. parasuis were adjusted to an initial OD<sub>600</sub> of 0.05, 0.125, or 149 0.25 in BHI+ broth. Diluted G. parasuis was plated in triplicate on a Nunc 96-well flat bottom 150 plate (Thermo Fisher Scientific Inc., Waltham, MA) and incubated statically for 48 hours at 37°C 151 with 5% CO<sub>2</sub>. Cultures were gently removed from the plate and washed three times with sterile 152 PBS. Biofilm was fixed with 100% ethanol, allowed to dry for 10 minutes, and stained with 153 0.1% crystal violet. After 15 minutes at room temperature, plates were washed gently three times 154 with PBS and allowed to dry overnight. Crystal violet was eluted from the biofilm with 150 uL 155 of 100% ethanol for 10 minutes. The elution (120 uL) was transferred to a new 96 well plate and 156 absorbance measured at 538 nm with a SpectraMax M5 (Molecular Devices, LLC, Sunnyvale,

- 157 CA). Three independent replicates were performed.
- 158 **Complement mediated killing**

 $\triangleleft$ 

Infection and Immunity

 $\mathbb{A}$ 

159	To assess sensitivity to complement mediated killing, G. parasuis cultures were treated with
160	guinea pig serum (GPS) (Quidel, San Diego, CA). Heat inactivated GPS (30 minutes at 56°C)
161	was used as a negative control. G. parasuis cultures were grown on BHI+ plates and suspended
162	in PBS to reach an OD <sub>600</sub> of 0.42 ( $1x10^8$ bacteria/mL). In a 96-well plate, 90 uL of GPS was
163	added to 10 uL of G. parasuis (approximately 10 <sup>6</sup> CFU). The G. parasuis and GPS incubated for
164	1 hour at 37°C, 5% CO <sub>2</sub> , 100 rpm shaking. Serial dilutions were plated on BHI+ plates.
165	Adherence capacity to porcine alveolar macrophage cell line (3D4/31 cells)
166	The interaction of G. parasuis HS069 and HS069 $\Delta$ cap with porcine alveolar macrophages was
167	tested in vitro using the 3D4/31 cell line (ATCC, Manassas, VA). 3D4/31 cells were maintained
168	in complete Advanced RPMI 1640 (Thermo Fisher Scientific Inc., Waltham, MA) as per
169	ATCC's recommendations. For the assay, 3D4/31 cells were plated into 4-well chamber slides
170	(ibidi USA Inc., Madison, WI) at $5 \times 10^5$ cells/mL and allowed to adhere overnight. G. parasuis
171	HS069 and HS069∆cap were added to the chambers to obtain an MOI of 10:1 and incubated for
172	1 hour at 37°C and 5% CO <sub>2</sub> . After incubating, 3D4/31 cells were washed to remove non-adherent
173	bacteria and chamber slides were placed on ice. G. parasuis cells were incubated with mouse
174	monocolonal antibody to the outer membrane protein P5 (provided by M. Gottschalk) for 30
175	minutes at 4°C followed by incubation with goat anti-mouse IgG3 (SouthernBiotech,
176	Birmingham, AL) for 30 minutes at 4°C. Cells were fixed with ice cold 50:50 methanol:acetone
177	for 10 minutes and dried. Images were taken using Nikon AR1+Si confocal microscope and
178	evaluated using the NIS Elements software (Nikon Instruments Inc., Melville, NY). Bacterial
179	intensity was evaluated using 10 random views.
180	Phagocytosis assessment using primary porcine alveolar macrophages
181	Porcine alveolar macrophages (PAMs) were isolated as previously described (25, 26), with

182	modifications. Briefly, the lungs of healthy pigs were flushed with PBS repeatedly until around
183	250 mL of fluid was collected. The lavage fluid was centrifuged at 1000 RPM for 10 minutes.
184	The pellet was washed twice and resuspended in complete RPMI-1640 medium (10% fetal
185	bovine serum, 1 $\mu$ g/mL fungizone, 100 U/mL penicillin, and 100 $\mu$ g/mL streptomycin). PAMs
186	were allowed to adhere to petri dishes for 2 hours at 37° C with 5% CO <sub>2</sub> . After 2 hours, media
187	and non-adherent cells were aspirated and adherent cells were washed with complete RPMI.
188	Adherent cells were removed via cell scraping, washed twice with PBS, and resuspended in
189	RPMI without antibiotics. Cells were counted and scored for viability using the Countess II
190	Automated Cell Counter (Invitrogen, Carlsbad, CA). PAMs were plated into 48-well plates with
191	$5 \times 10^5$ PAMs per well and allowed to adhere for 20 minutes prior to starting the assay.
192	Bacterial stocks were generated by suspending agar grown HS069 and HS069∆cap in
193	PBS with 50% glycerol at an OD <sub>600</sub> of 0.42. The stocks were quantified via serial dilution and
194	frozen at -80° C until use. HS069 or HS069∆cap stocks were diluted to obtain an MOI of 10:1 in
195	250 $\mu$ L total volume per well (approximately 5x10 <sup>6</sup> CFU/well).
196	To assess phagocytosis, the media was aspirated and RPMI containing G. parasuis was
197	added to each well. The PAMs were incubated with the bacteria for 1 or 2 hours and the
198	supernatant was used to quantify non-phagocytosed bacteria. PAMs were isolated from four
199	different animals and 2-4 replicates were completed per animal for each isolate. The CFU/mL
200	was quantified for HS069 and HS069 $\Delta$ cap inocula. The log fold reduction was calculated by
201	subtracting the remaining bacteria at hour 1 or 2 from the initial inoculum.
202	G. parasuis challenge
203	All experiments were approved by the National Animal Disease Center's Institutional Animal
204	Care and Use Committee. Caesarian-derived, colostrum-deprived (CDCD) pigs were derived at

 $\overline{\triangleleft}$ 

205	the National Animal Disease Center. At 4 weeks of age, pigs were intranasally challenged with 2
206	mL (1 mL per nostril) of 1x10 <sup>8</sup> CFU/mL G. parasuis HS069 (4 pigs) or HS069∆cap (5 pigs)
207	suspended in PBS. Pigs were monitored for clinical signs (lameness, respiratory distress,
208	lethargy, neurologic signs) and humanely euthanized when systemic signs of disease were noted.
209	At necropsy, gross lesions were recorded and serum, nasal swabs, serosal swabs, joint fluid, lung
210	lavage, and cerebral spinal fluid samples were obtained and plated for CFU counts. Serum and
211	nasal swab samples were taken on day 0 and day 21 post-challenge. To investigate the vaccine
212	potential of HS069∆cap, the pigs surviving challenge with HS069∆cap (5 pigs) were intranasally
213	challenged with 2 mL (1 mL per nostril) of $1 \times 10^8$ of G. parasuis HS069 wild type on day 21
214	post-challenge with HS069∆cap. Pigs were monitored and treated as described above
215	A follow up study was conducted to evaluate nasal colonization of HS069∆cap in CDCD
216	pigs. At 6 weeks of age, 6 pigs were inoculated intranasally with 2 mL (1 mL per nostril) of
217	$1 \times 10^{8}$ CFU/mL suspension of G. parasuis HS069 $\Delta$ cap in PBS. Nasal swabs were obtained on
218	day 0, 1, 3, 5, 7, and 14 post-challenge for G. parasuis detection. G. parasuis species specific
219	PCR was run on these samples to detect bacterial colonization utilizing the primer set described
220	by Howell et al. (27). Briefly, DNA was extracted from 50 $\mu$ L of nasal swab samples using the
221	MagMAX Pathogen RNA/DNA Kit (Thermo Fisher Scientific Inc., Waltham, MA). Extracted
222	DNA was screened as previously described using G. parasuis species specific primers:
223	HPS_219690793-F (5'-ACAACCTGCAAGTACTTATCGGGAT-3') and HPS_219690793-R
224	(5'-TAGCCTCCTGTCTGATATTCCCACG-3') (27).
225	ELISA for serum antibody titer
226	Nunc MaxiSorp plates (Thermo Fisher Scientific Inc., Waltham, MA) were coated with 0.5

227 mg/mL of HS069∆cap sonicate in 100 mM carbonate-bicarbonate buffer (pH 9.6) at 4°C

228	overnight. Plates were washed with 0.05% Tween 20 in PBS (PBST) followed by blocking for 1
229	hour at 37°C with 2% bovine serum albumin (BSA) in PBST. After washing with PBST, serum
230	samples were serially diluted in 1% BSA/PBST and applied to wells for 2 hours at 37°C. Plates
231	were washed with PBST and HRP-conjugated secondary goat anti-swine IgG antibody (SeraCare
232	Life Sciences, Milford, MA) was diluted 1:50,000 in 1% BSA/PBST added and incubated for 1
233	hour at 37°C. ELISAs were developed using tetramethylbenzidine (TMB) substrate (Thermo
234	Fisher Scientific Inc., Waltham, MA). TMB was added to each well, incubated at room
235	temperature for 15 minutes, and the reaction halted with sulfuric acid (2 N). Absorbance 450 nm
236	was measured on a SpectraMax M5 (Molecular Devices, LLC, Sunnyvale, CA).
237	Statistical analysis
238	Statistical analysis was completed using GraphPad Prism 7.03 (GraphPad Software, La Jolla,
239	CA). Biofilm formation was compared using an unpaired t test. Complement mediated killing
240	was evaluated as a log-fold reduction in G. parasuis between heat inactivated GPS and GPS and
241	analyzed using an unpaired t test. Phagocytosis was evaluated using log-fold reduction in $G$ .
242	parasuis between the inoculum and PAM incubated wells. The difference in reduction between
243	HS069 and HS069∆cap was compared using an ordinary one-way ANOVA. Comparison of
244	adherence to porcine alveolar macrophages was completed using unpaired t tests comparing both
245	bacterial cells per 3D4/31 cell and fluorescent intensity per 3D4/31 cell. Welch's corrections
246	were used to account for differences in standard deviation when necessary. Results were
247	considered significant at a p-value of $p < 0.05$ .
248	

 $\mathbb{A}$ 

### 249 Results

#### 250 Development and confirmation of HS069 capsule mutant

251 The capsule locus of HS069 was removed by deleting the sequence from *neuA\_3* to *etk* 

252 (alternatively *wzc* or *wzs*) (Figure 1-A), which removed the biosynthesis and glycosyltransferase

253 proteins contained within the serovar 5 capsule locus. The deleted sequence was confirmed with

254 whole genome sequencing using the PacBio sequencing platform. When the wild type and

HS069∆cap genomes were compared, no HS069∆cap reads mapped to the region of the capsule

locus (Figure 1-B).

257 Transmission electron microscopy (TEM) was also performed to phenotypically confirm

the deletion of the capsule locus. In Figure 2, the surface of the HS069 wild type cells is irregular

Downloaded from http://iai.asm.org/ on March 10, 2020 at Royal Veterinary College

and thickened as compared to HS069∆cap. This confirmed the absence of capsular

260 polysaccharide of the cell surface of  $HS069\Delta cap$ .

#### 261 Growth characteristics and cellular morphology

262 Comparison of the growth kinetics of G. parasuis HS069 and HS069 $\Delta$ cap grown in BHI+ broth

263 indicated there was no alteration in cellular proliferation associated with deletion of the capsule

264 locus (Supplemental Figure 1).

#### 265 **Biofilm formation**

266 Evaluation of static biofilm production indicated similar capacity for G. parasuis isolates to

267 produce biofilm at all starting cell densities tested (0.05, 0.125, and 0.25) (data not shown).

268 Statistical evaluation of static biofilm production by HS069 and HS069∆cap grown from an

269 initial cell density of 0.05 indicated a significant enhancement in production associated with loss

of capsular polysaccharide production (p = 0.0193) (Figure 3).

271 Complement mediated killing

283	counts ( $p = 0.0594$ ) or compared for fluorescent intensity ( $p = 0.4296$ ).
284	Phagocytosis by primary porcine alveolar macrophages

285 Changes in susceptibility to phagocytosis were assessed by incubation with isolated primary

Sensitivity to complement mediated killing (serum sensitivity) was evaluated using non-treated

and heat inactivated GPS. A significant increase in sensitivity to complement killing was noted

Confocal microscopy was used to evaluate the adherence capacity of HS069 and HS069∆cap to

porcine alveolar macrophages (3D4/31 cells). A distinct difference in the pattern of attachment

Because of the aggregation of HS069 $\Delta$ cap, adherence was evaluated both as a bacterial count per

was visualized between HS069 and HS069\(\Delta cap (Figure 5), with HS069\(\Delta cap producing ))

aggregates of bacteria (Figure 6B) that were not noted with HS069 wild type (Figure 6A).

3D4/31 cell and fluorescent intensity per 3D4/31 cell. There was no statistically significant

difference in adherence capacity when HS069 and HS069∆cap were compared for bacterial

for HS069 $\Delta$ cap as compared to wild type HS069 (p = 0.0207) (Figure 4).

Adherence capacity to porcine alveolar macrophage cell line

- 286 porcine alveolar macrophages. After one hour of incubation, there was no difference in
- 287 phagocytosis between HS069 and HS069 $\Delta$ cap (P = 0.93); however, after two hours of
- 288 incubation, significantly more HS069∆cap were phagocytosed compared with HS069 wild type
- 289 (P < 0.01) (Figure 7).

#### 290 Virulence assessment

- 291 To assess the virulence of HS069 $\Delta$ cap as compared to the parent strain, a total of 11 CDCD pigs
- 292 were challenged with HS069∆cap and four with wild type HS069. The parent strain resulted in
- 293 100% mortality by day 2 post-challenge, while animals challenged with HS069∆cap showed no
- 294 clinical signs of G. parasuis infection and survived until the end of the study (20 days post-

 $\triangleleft$ 

296	Colonization and immune stimulation
297	A second study was conducted to evaluate nasal colonization of HS069∆cap in CDCD pigs. The
298	presence of G. parasuis in nasal wash samples was assessed by PCR. Species specific primers
299	detected G. parasuis on days 1 (1 pig) and 3 (2 pigs) post-challenge; however, all pigs were
300	negative by PCR by day 5 post-challenge.
301	Serum antibody titer for animals challenged with HS069∆cap was determined at day 0, 7,
302	14, and 21 post-challenge (Figure 8). A mild increase in serum antibody to HS069∆cap sonicate
303	was seen over the study period with the average $Log_{10}$ titer rising from $3.121\pm0.336$ to
304	3.572±0.250. However, upon intranasal challenge of HS069∆cap inoculated animals with wild
305	type G. parasuis HS069, all animals succumbed to disease by 3 days post challenge.

306

# 307 Discussion

308	Capsular polysaccharide is an important factor for the survival and virulence of many bacteria. It
309	is known to function in adhesion and immune evasion through resistance to complement killing
310	and phagocytosis (11). In this study, we sought to better evaluate the function of capsule for $G$ .
311	parasuis, the causative agent of Glässer's Disease in pigs. Capsule has been correlated with
312	virulence, with some serovars associated with disease and others with nasal colonization (3, 5,
313	6). The importance of capsule for G. parasuis was previously investigated in the serovar 5 strain
314	SH0165 (10). Wang and colleagues found SH0165∆capD to be less serum resistant and non-
315	virulent in a pig challenge, compared to the highly virulent parent strain (10). To confirm and
316	expand on these findings and better understand how capsule contributes to G. parasuis disease,
317	we generated a capsular mutant of the virulent serovar 5 strain HS069 followed by evaluation of
318	sensitivity to complement killing and macrophage adhesion in vitro as well as virulence,
319	colonization, and immune stimulation in vivo.
320	Here, the virulence of HS069∆cap was assessed with a combination of <i>in vitro</i> assays and
321	an <i>in vivo</i> challenge. We found that, similar to previous reports, HS069∆cap was markedly less
322	virulent in a pig challenge than the encapsulated parent strain. This confirmed what was noted by
323	Wang and colleagues with SH0165\(\Delta\)cap (10). Reduced virulence of capsule deficient isolates has
324	been attributed in part to the marked increase in serum sensitivity in non-encapsulated $G$ .
325	parasuis strains, which was seen with both HS069∆cap (Figure 4) and SH0165∆cap (10).
326	Resistance to complement killing enables bacteria that penetrate mucosal defenses to better
327	survive and disseminate to systemic sites, such as the central nervous system, joints, and serosal
328	surfaces, as seen in G. parasuis infection.
329	Virulence has also been correlated with susceptibility to porcine alveolar macrophages

 $\mathbb{A}$ 

Infection and Immunity

330

331	interaction between $HS069\Delta$ cap and porcine alveolar macrophages, we examined the adherence
332	capacity of HS069∆cap and the parent strain to 3D4/31 cells (Figure 6). In this investigation,
333	HS069 and HS069∆cap adhered equivalently, indicating the capsule is not playing a role in the
334	interaction between G. parasuis HS069 and 3D4/31 cells. This analysis was made more
335	complicated by the aggregation of HS069∆cap (Figure 5); however, through analysis of
336	fluorescent intensity, we were able to account for aggregated bacteria (Figure 6B). We also
337	evaluated HS069 and HS069∆cap for susceptibility to phagocytosis by primary PAMs, which
338	revealed significantly more HS069 $\Delta$ cap was phagocytosed over two hours than HS069 wild
339	type. This indicates the importance of G. parasuis capsule in protection against macrophage
340	phagocytosis, which has not been shown previously in G. parasuis.
341	Additionally, we investigated the persistence of G. parasuis HS069 $\Delta$ cap in the nasal
342	passageways, which indicated the importance of capsular polysaccharide not just in systemic
343	infection, but also to colonization. Though biofilm production was enhanced for HS069 $\Delta$ cap
344	(Figure 3), it did not contribute to persistent nasal colonization and HS069∆cap was cleared from
345	all pigs in the second study by 5 days post-inoculation. This contrasts with colonization of the
346	parent strain, which can persist in the nasal tract of vaccinated pigs (4/5 animals) through 11
347	days post-challenge (data not shown). Previous results assessing the role of capsule in
348	colonization and adherence of other bacterial species have conflicted, with some studies
349	reporting deficient colonization seen with capsular mutants and others indicating an increased
350	capacity for adhesion to cell lines in vitro (12, 29-32). It has been hypothesized that the absence
351	of capsule may increase the exposure of surface adhesins that contribute to adherence in vitro;
352	however, most studies evaluated only in vitro adherence and have not investigated the effect of

(28), which serve as the first line of defense during pulmonary infection. To investigate the

 $\overline{\mathbb{A}}$ 

353

354

355 Streptococcus pneumoniae (12). 356 The lack of virulence seen with G. parasuis capsular mutants would potentially make 357 them a good candidate for an attenuated live vaccine; however, our investigation showed only a 358 mild increase in G. parasuis serum antibody titer over the 21 day study period (Figure 8) with an 359 average  $Log_{10}$  titer at 21 days post-inoculation of  $3.572\pm0.250$ . The titers seen in animals 360 inoculated with HS069\Delta cap are low when compared with other studies in which animals were 361 vaccinated with a single dose HS069 bacterin (average Log<sub>10</sub> titer 21 days post vaccination 362  $4.221\pm0.377$ ) or after boost vaccination (average Log<sub>10</sub> day 42 titer  $4.752\pm0.190$ ), which has 363 shown protection against homologous challenge. Low titers associated with HS069\(Lambda) cap are 364 likely due to its rapid clearance from the nasal cavity, which would limit interaction with 365 immune cells and development of an adaptive immune response. Furthermore, when pigs 366 inoculated with HS069∆cap were challenged with the parent strain, we saw no protection from 367 G. parasuis disease, indicating the antibody response generated was not protective. 368 It is important to note, this evaluation of the importance of capsule in G. parasuis 369 colonization and infection involved the generation and use of a mutant deficient in all genes of 370 the capsule locus. Because of this, we cannot eliminate the possibility that there are alternative 371 functions for genes within the capsule locus that may be contributing to the phenotypes we 372 observed in this study. Additionally, because of the size of the capsule locus, a mutant 373 complemented with the deleted genes was not generated and comparisons can only be made 374 between the wild type and the mutant. 375 Conclusions

capsule in colonization in vivo. Our findings in this study indicate capsule may play a significant

role in persistent colonization with G. parasuis in vivo, similar to that seen previously with

 $\overline{\triangleleft}$ 

376 This investigation of the G. parasuis capsule mutant HS069∆cap confirms the importance 377 of capsule to a fully virulent phenotype in vivo that has been seen previously with 378 SH0615\(\Delta\)capD. Capsular polysaccharide plays an important role in resistance to complement 379 killing and phagocytosis, which may be a key factor in the dissemination of G. parasuis during 380 infection to systemic sites. In this study, we also found capsule to be an essential factor in G. 381 parasuis HS069 for persistent colonization of the swine nasal cavity. However, because of the 382 rapid clearance of HS069∆cap from the nasal cavity, generation of antibody was minimal and no 383 protection was provided against challenge with the parent strain making HS069 $\Delta$ cap a poor 384 modified live vaccine candidate.
